U.S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE / PUBLIC HEALTH SERVICE HEALTH SERVICES AND MENTAL HEALTH ADMINISTRATION
DATE OF RELEASE: APRIL 11, 1969 - ATLANTA, GEORGIA 30333

EPIDEMIOLOGIC NOTES AND REPORTS BOTULISM - Tarrant County, Texas

On March 31, 1969, in Tarrant County, a 25-year-old man developed an illness characterized by dizziness and vertigo followed within 8 hours by blurred vision, diplopia, and dysphagia. By the following morning generalized weakness and progressive respiratory distress ensued and he was hospitalized. He remained afebrile and alert. On April 2 he was transferred to the intensive care unit of a hospital in Dallas where tracheal intubation and assisted ventilation were required. On April 4 a tracheostomy with controlled ventilation was necessary. A repeat lumbar puncture showed normal cerebrospinal fluid. His pupils were dilated and reacted sluggishly to light. There was complete ophthalmoplegia and lingual and pharyngeal

paralysis. Profound skeletal muscle weakness was present. The plantar responses were bilaterally flexor. The patient remained alert throughout his illness and no sensory deficits were present.

On April 4 botulism was diagnosed and trivalent (A,B, and E) *Clostridium botulinum* antiserum was administered. The following day the diagnosis was confirmed (Continued on page 114)

TABLE I. CASES OF SPECIFIED NOTIFIABLE DISEASES: UNITED STATES
(Cumulative totals include revised and delayed reports through previous weeks)

DISEASE	14th WEEK ENDED		MEDIAN 1964 - 1968	CUMULATIVE, FIRST 14 WEEKS

Data exclude report from Alaska.

BOTULISM - (Continued from front page)

when type A botulism toxin was demonstrated in the patient's serum using the mouse protection test. Serum taken from the patient 18 hours after treatment no longer contained demonstrable botulism toxin. The patient expired on April 9.

(Reported by G. J. Vakkur, M.D., Attending Physician; Staff, Tarrant County Health Department; M. S. Dickerson, M.D., Chief, Division of Preventable Disease Control, Texas Department of Health; Anaerobic Bacteriology Laboratory, Bacterial Reference Unit, Laboratory Division, NCDC; and an EIS Officer.)

Editor's Note:

The source of the type A toxin has not been discovered. The patient and his wife denied any ingestion of home-canned foods. The case is under intensive epidemiologic investigation by officials of the local and state health departments. It would behoove all physicians and public health officials in the area to be alert for any other cases compatible with botulism.

SURVEILLANCE SUMMARY
HUMAN BRUCELLOSIS - United States 1968*

In 1968, a total of 231 human cases of brucellosis were reported to the NCDC, a decrease from the 248 cases reported in 1967 (MMWR, Vol. 17, No. 10) (Figure 1). In 1968, 34 states reported one or more cases with six states (California, Georgia, Iowa, North Dakota, Tennessee, Texas, and Virginia) recording 71 percent of the cases. The greatest increase in cases over 1967 occurred in Virginia with the largest decrease in Texas (Table 1). In 1968, more cases, 30, occurred in June than in any other month with the fewest cases, 4, occurring in November (Figure 2). This distribution is similar to that of 1967 when more cases, 35, occurred in June than in any other month, but the fewest cases, 12, occurred in February.

Brucellosis surveillance reports on 187 of the 231 cases were submitted to the Zoonoses Surveillance Unit, NCDC. Of the 187 cases, 158 were males, and 131 of the 158 were between 20 and 60 years of age (Table 2). Of the 158 males, 105 were packinghouse workers. In 73 cases among the male packinghouse workers (70 percent), swine were listed as the most probable source of infection, while only nine workers (9 percent) were exposed to cattle as the single most probable source. Of the total 187 cattle, 81 listed swine as the most likely source, 25 listed cattle only, 21 noted cattle and swine, and 25 noted dairy products. Of 75 persons on whom blood cultures were performed, 42 had cultures positive for a *Brucella* species.

TOTALS	6.4	231	-27

*Provisional data

*One case with onset and recrudescence in 1968 counted as two cases.

The distribution of total cases with exposure to swine (43 percent) and cattle (13 percent) was generally reflected in the distribution of human isolates of *Br. suis* (48 percent) and *Br. abortus* (17 percent). In the 169 cases where symptoms were recorded, fever, chills, and malaise predominated.

(Reported by the Veterinary Public Health Section, and Statistics Section, Epidemiology Program, NCDC.)

*Preliminary data.

INTERNATIONAL NOTES

BOLIVIAN HEMORRHAGIC FEVER – La Cayoba, Bolivia

An outbreak of Bolivian hemorrhagic fever (BHF) occurred during January and February in La Cayoba, Bolivia, a small agricultural community, 40 km north of Magdalena in the Province of Itenez, Department of Beni. There were 10 suspected cases with six deaths¹ among the 245 residents. Virus, isolated from the spleen of one fatal case and from the blood of two other subsequently fatal cases, was identified as Machupo virus, causative agent of BHF. Machupo virus was also isolated from 12 of 40 *Calomys callosus* rodents trapped inside the houses of La Cayoba. Seven of the 12 positive rodents were caught in one house where three cases had occurred (two were fatal). Prior to the outbreak, only one of 120 La Cayoba residents had Machupo virus neutralizing antibodies.

Approximately 100 residents fled from the town during the outbreak and the remaining 145 were quarantined for 30 days in a deserted agricultural experimental station, 4 km north of Magdalena. Food was supplied by friends and relatives in Magdalena. A team of five Machupo-immune persons, employed by the hemorrhagic fever commission since 1965 to carry out rodent control measures in San Joaquin, was sent to La Cayoba. Kill traps and poison were used to eliminate rodents. Corn, rice, yucca, and banana crops were harvested and destroyed so that they would not be available to support rodent populations. The control measures, although drastic economically and psychologically to the residents of La Cayoba, appear to have stopped the outbreak and avoided spread to Magdalena.

(Reported by Luis Valverde Chinel, M.D., Chief, Hemorrhagic Fever Commission, La Paz, Bolivia; and Patricia Ann Webb, M.D., Middle America Research Unit, Balboa Heights, Canal Zone.)

Editorial Comment:

Machupo virus is transmitted to man by contact with the rodent *Calomys callosus*; human to human transmission is rare.² The incubation period is approximately 7 to 15 days.

Ecologically, the isolated community of La Cayoba resembles Orobayaya, a town 45 km to the east, where the disease occurred with devastating intensity in 1960-1962 (107 cases with 44 deaths among 600 residents).³
